THE
FLOATING-RATE
FAULT LINE

PRIVATE CREDIT RISK EDUCATIONAL MATERIAL

SOFR, Private Credit, BDCs, and the Risk Curve

Source Note. This pamphlet is an independent educational synthesis from a user-supplied transcript of a [Casual Finance](#) video covering [Treasury yields](#), [SOFR](#), private credit, PIK interest, BDCs, and credit stress, combined with public [FRED](#) rate and spread data and Nasdaq public quote pages for ETF/BDC proxies. Updated July 14, 2026; original v1 is archived separately. It is a monitoring framework, not financial advice, a recommendation, or a claim of future performance.

The Floating-Rate Fault Line

A medium/long-term risk setup for [SOFR](#), private credit, BDCs, and the public-market proxies that may signal when private marks finally catch up to public stress.

Pamphlet Contents

1. The setup: why the private-credit stress story is a medium/long-term thesis, not a one-day headline.
2. The mechanism: [SOFR](#), floating-rate debt, PIK interest, private marks, and BDC payout optics.
3. The risk curve: a staged map from funding pressure to public repricing.
4. The progress check: whether July data has moved the idea closer to confirmation or invalidation.
5. The charts: overlaid [rates](#), curve pressure, spreads, BDC proxies, and individual names.
6. The trigger sheet: confirmation, invalidation, and what would move the thesis from latent to active.

July 2026 Progress Check

The updated read is mixed rather than dramatic. The funding-pressure side of the thesis is still alive: [SOFR](#) was 3.55%, effective fed funds was 3.62%, the [2Y Treasury](#) was 4.21%, the [10Y Treasury](#) was 4.56%, and the [30Y Treasury](#) was 5.06% on the latest FRED observations available during this update. That is not the relief path borrowers would want.

But the public confirmation layer is not yet disorderly. High-yield OAS was 2.69% and investment-grade OAS was 0.77% on the same FRED window, which says the public credit market is still pricing contained stress. From the first trading day after the original pamphlet date, June 15, 2026, through the latest Nasdaq close on July 13, 2026, [BIZD](#) fell 0.56%, [HYG](#) fell 0.65%, and [BKLN](#) fell 0.10%. That is mild pressure, not a break.

FUNDING PRESSURE SOFR 3.55% FRED, JUL 10, 2026	CREDIT SPREAD CHECK HY OAS 2.69% CONTAINED, NOT YET STRESS CONFIRMATION	BDC PROXY SINCE V1 BIZD -0.56% JUN 15 TO JUL 13, 2026
---	--	--

Gauge	Latest Read	Progress Read
Front-end funding pressure	SOFR 3.55%, DEF 3.62%, 2Y 4.21%.	Pressure remains active. Floating-rate borrowers have not received clean cash-flow relief.
Long-end pressure	10Y 4.56%, 30Y 5.06%.	The refinancing clock still matters. Lower front-end expectations have not erased long-end pressure.
Public credit confirmation	HY OAS 2.69%, IG OAS 0.77%.	Not confirmed at the index-spread layer. The stress thesis remains a watch-list framework rather than an active spread break.
ETF proxy surface	BIZD \$12.47 (-0.56%), HYG \$79.52 (-0.65%), BKLN \$20.44 (-0.10%).	Mild slippage, not a collapse. The public proxy layer is leaning cautious, but it is not screaming.
Spillover check	KRE \$75.12 (+4.00%) while SPY \$749.17 (-0.75%).	Regional banks did not confirm a broad credit accident over this window.
BDC dispersion	BXSL -1.64%, OBDC -1.99%, FSK -1.10%; MAIN +2.38%, HTGC +2.78%, GBDC +1.57%.	The signal is dispersion, not uniform capitulation. That argues for name-level monitoring and reported-credit metrics.

July Progress Check: Public Proxy Returns Since V1

Close-to-close move from June 15, 2026 to July 13, 2026. Mild pressure, mixed BDC dispersion, no broad break.

Source: Nasdaq public quote/historical pages for BIZD, HYG, BKLN, KRE, SPY, ARCC, BXSL, OBDC, FSK, MAIN, HTGC, and GBDC. Pulled July 14, 2026.

Proxy returns from the first trading day after the original pamphlet date through the latest Nasdaq close available during this update. The point is not a broad break; it is mild public proxy pressure plus name-level dispersion.

Current status: the idea is progressing only in the sense that the rate-pressure premise has not gone away and weaker BDC proxies are not leading higher. It has not yet progressed into a confirmed public-credit break. The next evidence needs to come from widening spreads, weaker BDC relative strength, NAV pressure, rising non-accruals, higher PIK dependence, or refinancing concessions in the 2026-2029 maturity window.

1. The Setup

The transcript's core idea is simple: the price of money has been repriced, but the most fragile balance sheets do not all reprice visibly at the same time. SOFR hits floating-rate borrowers immediately. Private-credit marks, BDC NAVs, dividend coverage, and public proxy prices may lag.

The medium/long-term setup is therefore not "rates are high, so something must break." The setup is a timing curve: funding pressure first, borrower cash-flow stress second, accounting accommodation third, public-market recognition fourth.

The private-credit market matters because many loans sit outside daily public price discovery. When those loans are floating-rate, the debt service burden can rise quickly, while the visible damage may appear slowly through PIK interest, non-accruals, amendments, NAV marks, redemptions, or dividend pressure.

2. The Mechanism

SOFR is the pressure valve. A floating-rate loan uses a benchmark, commonly [SOFR](#), plus a spread. If [SOFR](#) rises or stays elevated, the borrower's interest cost stays elevated. The lender may still report income, but the borrower's cash-flow cushion shrinks.

PIK is the smoke chamber. Payment-in-kind interest can allow a borrower to avoid cash interest by adding unpaid interest to principal. That may prevent an immediate default trigger, but it also turns cash income into a claim on future repayment.

BDC optics are the public window. Business development companies and BDC ETFs are not the whole private-credit universe, but they are tradable proxy surfaces. They let the market express concern before every private loan is marked down.

The maturity wall is the clock. The transcript frames 2026-2029 as the refinancing window to watch. The key question is whether lower [rates](#) arrive early enough, and whether lower [rates](#) are relief or recession confirmation.

3. Projected Risk Curve

Projected Risk Curve: From Funding Pressure to Market Recognition

A sequence for monitoring confirmation, not a guaranteed path.

Projected risk curve. The curve is not a forecast path; it is a monitoring sequence for where stress should surface if the thesis is working.

The technically sound version of this thesis is staged. Do not demand that every signal fire at once. If private credit is the concealed stress channel, the first signals should be rates and borrower mechanics. The later signals should be spread widening, BDC underperformance, NAV pressure, and more explicit defaults.

4. Chart Pack

SOFR, Fed Funds, and the Front-End Signal

Daily observations, weekly sampled. Funding pressure hits floating-rate borrowers first.

Source: FRED series SOFR, DFF, and DGS2.

SOFR, Fed funds, and 2Y Treasury yield. This chart tracks whether the floating-rate burden is actually easing.

Treasury Curve Pressure

2Y, 10Y, and 30Y Treasury yields. The long end prices duration, inflation, and fiscal trust.

Treasury curve pressure. The 2Y captures policy expectations; the 10Y anchors broad risk; the 30Y tests long-run fiscal and inflation trust.

Credit Spread Confirmation Versus Funding Pressure

High-yield and investment-grade OAS overlaid with SOFR. Stress often confirms after funding pain.

Credit spread confirmation versus funding pressure. A dangerous configuration is high funding pressure with spreads that remain too calm.

Public Proxies for the Private-Credit Stress Channel

Adjusted close proxies, normalized to 100. Public prices are noisy but update faster than private marks.

Public proxies. [BIZD](#), [HYG](#), [BKLN](#), [KRE](#), and [SPY](#) are noisy, but they update faster than private marks.

BDC Names to Compare, Not Worship

Representative publicly traded BDCs, normalized to 100 from 2024. Dispersion is the signal.

BDC names. The purpose is not to worship one ticker; the purpose is to watch dispersion, relative weakness, and who fails to recover.

5. Names and Proxies

Signal	Names / Series	Why It Matters
Funding pressure	SOFR , DFE , 2Y Treasury	Shows whether floating-rate borrowers are actually getting relief.
Long-end pressure	10Y , 30Y Treasury	Long rates govern discounting, duration pain, and refinancing psychology.
Credit confirmation	HY OAS , IG OAS , HYG , BKLN	Confirms whether stress is moving from funding math into public credit pricing.
Private-credit proxy	BIZD	BDC ETF surface for the broader lending stress story.
BDC dispersion	ARCC , BXML , OBDC , FSK , MAIN , HTGC , GBDC	Watch relative strength, dividend/NAV pressure, non-accruals, and PIK exposure by name.
Spillover	KRE , SPY	Regional banks and broad risk appetite show whether private stress stays contained.

6. Confirmation and Invalidation

Current Read

As of the July 14, 2026 update, the thesis remains live but not fully confirmed. The funding-pressure indicators are still restrictive, while public credit spreads and broad proxy prices have not broken. The right posture is therefore conditional: keep the framework, sharpen the triggers, and avoid pretending that a contained spread market has already delivered confirmation.

Scenario Forecasting Aids

For a prospectus-style risk section or investment memo, the point is not to pretend that the future is a single line. The point is to translate the conditional thesis into visible paths: what confirmation would look like, what a muddled middle would look like, and what would invalidate the stress case.

Scenario Forecast: Confirmation Versus Relief

Illustrative condition score: SOFR persistence, spread stress, BDC dispersion, and reported credit strain.

Illustrative scenario simulation for risk monitoring only; not a price target, valuation, forecast, recommendation, or guarantee.

Scenario confirmation score. This simulated monitor compresses [SOFR](#) persistence, credit-spread widening, BDC dispersion, and reported stress into one conditional score. A rising line means the stress thesis is gaining confirmation; a falling line means the relief path is doing the work.

Scenario Forecast: Public Proxy Response

Simulated normalized paths for BDC/credit-risk proxy behavior under stress, middle, and relief conditions.

Public proxy response simulation. The downside path shows BDC proxy weakness leading broader credit recognition; the relief path shows the opposite condition: funding relief without disorderly spread widening.

Scenario	What It Should Look Like	Prospectus-Style Use
Confirmation stress	<u>SOFR</u> remains sticky, spreads widen, BDCs lose relative strength, and PIK/non-accrual metrics rise.	Downside case and risk-factor support.
Muddled middle	<u>Rates</u> ease slowly, spreads drift wider but not violently, and BDC dispersion becomes more important than index direction.	Base case with monitoring triggers.
Invalidation relief	<u>SOFR</u> falls durably, refinancing windows reopen, and BDC proxies recover without a delayed credit-spread break.	Relief case and thesis invalidation language.

Confirmation Path

- SOFR and Fed funds remain high enough that floating-rate borrowers do not receive meaningful cash-flow relief.
- 2Y yields stop falling while 10Y/30Y yields stay elevated, implying relief is not arriving cleanly across the curve.
- HY OAS and IG OAS begin to widen while BIZD and weaker BDC names underperform SPY and HYG.
- BDC reports show rising PIK dependence, non-accruals, dividend coverage strain, NAV marks, or amendment activity.
- The 2026-2029 refinancing window produces more restructurings rather than clean maturity extensions.

Invalidation or Relief Path

- SOFR falls materially and durably without a disorderly credit-spread widening.
- BDC proxies reclaim relative strength while reported PIK and non-accrual stress declines.

- [Credit spreads](#) remain contained because borrower cash flow improves, not because losses are hidden by accounting structure.
- Refinancing markets reopen for middle-market borrowers without forcing widespread lender concessions.

Closing: The Curve Is the Setup

The setup is not a single ticker. It is a sequence. If the thesis is real, [SOFR](#) and the curve should describe the pressure, [credit spreads](#) should begin to confirm it, BDC proxies should reveal market recognition, and reported private-credit metrics should eventually lose the ability to hide the stress.

That is the pamphlet's discipline: track the pressure, wait for confirmation, and respect invalidation. The hidden thing only becomes tradeable when the visible surfaces start to agree. For now, the pressure is visible, but the confirmation is still incomplete.

Updated July 14, 2026 with FRED observations available through July 10, 2026 and Nasdaq proxy closes through July 13, 2026. Original v1 archived separately. Educational research only; not financial advice.
